ABSTRACT: Objective: To summarize the scientific production on surgical procedures during the COVID-19 pandemic. Method: This is an integrative review conducted between September and November 2020 in the following databases: PubMed, Medical Literature Analysis and Retrieval System Online (MEDLINE), Latin American and Caribbean Health Sciences Literature (Literatura Latino-Americana e do Caribe em Ciências da Saúde — LILACS), and Nursing Database (Base de Dados em Enfermagem — BDENF); combining the descriptors: “coronavirus and perioperative care”; “coronavirus and operating room nursing”; “perioperative care and operating room nursing”, connected by the Boolean operator “AND”. We retrieved 858 articles and included 15 in the sample. The level of scientific evidence was applied. Results: The publications had methods such as clinical recommendations, case reports, and observational studies, with level of evidence VI, indexed in the PubMed, LILACS, and MEDLINE databases. The articles provide recommendations on the management of surgical procedures, human resources, and materials for the working of the surgical center during the pandemic. Conclusions: We highlight the possibility of limiting elective surgical procedures, with access to rapid tests and effectiveness in protecting professionals. Keywords: Coronavirus infections. Surgicenters. Pandemics.

INTRODUCTION

Coronavirus is part of a family group of viruses, such as MERS-CoV and SARS-CoV, that usually affect some animals; however, in December 2019, the SARS-CoV-2 virus, which can be transmitted from person to person by direct contact, contaminated surfaces, handshakes, or the respiratory route — through droplets and aerosols from sneezing, phlegm, and coughing —, was discovered in Wuhan, China. Thus, the disease became globally known as coronavirus disease 2019 (COVID-19)\(^1\).

In this context, COVID-19 reached a high number of people worldwide and, on March 11, 2020, was considered a pandemic by the World Health Organization (WHO). Evidence showed that older patients with respiratory and cardiovascular conditions presented severe complications. Disease manifestations range from the lack of symptoms (asymptomatic patients) to flu syndrome, pneumonia, and even acute respiratory distress syndrome (ARDS), progressing to multisystem organ failure and, consequently, death\(^2\).

According to the coronavirus disease panel of the Ministry of Health (MoH), Brazil has over 16 million confirmed cases and more than 452 thousand deaths. We stress that the case count is performed daily, based on data provided by State Health Departments. This process is complex and dynamic, taking into account the plurality and limitations of each state and municipality\(^3\).

This scenario has impacted all health areas, especially the surgical field, which requires direct contact between patient and team and cannot be replaced by remote treatment. Therefore, the surgical workforce faced several challenges compared to other specialties\(^4\).

Moreover, the inordinate repercussions of the disease have produced a series of measures that had to be implemented in health facilities, either globally or at regional or local levels, to combat the COVID-19 pandemic in order to reduce its impacts\(^5\).

Although a wide range of studies has been published relating the pandemic to several areas, including the surgical center (SC), investigations from several countries, especially from Brazil, are needed to address what happens in the SC during patient care in times of COVID-19 since each country has its particularities, and the surgical specialty has been one of the most affected during the pandemic.

OBJECTIVE

To summarize the scientific production on surgical procedures during the COVID-19 pandemic.

METHOD

This is an integrative literature review with a descriptive design. To this end, we carefully followed the methodological process based on these steps:

- theme identification;
- elaboration of the research guiding question;
- establishment of criteria for inclusion and exclusion of studies/sampling or literature search;
- definition of the information to be extracted from the articles selected;
- assessment of the articles included in the integrative review;
- interpretation of results and knowledge review/synthesis, which allowed the critical analysis of findings\(^6\).

This research was carried out between September and November 2020 by students from the Nursing Undergraduate Program, under the guidance of two professors, for the subject “Special Topics in Health — Theoretical Notions of Surgical Center and Sterile Processing Department Nursing”, from an expanding university in Paraíba, Brazil.

This research was guided by the question: what has been published on national and international databases about the SC and the COVID-19 pandemic?

The time frame for the articles selected was 2020, as the focus of the COVID-19 pandemic.

To build the research corpus, we searched articles indexed online in the following databases: PubMed, Medical Literature Analysis and Retrieval System Online (MEDLINE), Latin American and Caribbean Health Sciences Literature (Literatura Latino-Americana e do Caribe em Ciências da Saúde — LILACS), and Nursing Database (Base de Dados em Enfermagem — BDENF) — the last three included in the Virtual Health Library (VHL).

We used the Health Sciences Descriptors (Descritores em Ciências da Saúde — DeCS), with the following keywords in English and their combinations linked by the Boolean operator “AND”: “coronavirus and perioperative care”; “coronavirus and surgery”; “perioperative care during COVID-19 pandemic”.

| REV. SOBIECC, SÃO PAULO. 2022;27:E2227746 | 2 |
and operating room nursing”; “perioperative care and operating room nursing”, in all databases selected.

The inclusion criteria were established considering full articles available online in Portuguese, Spanish, and English, addressing the guiding question. We excluded dissertations, theses, abstracts, unavailable texts, publications in other languages, and those that did not address the proposed theme.

Thus, 858 articles indexed in the databases consulted were retrieved — 302 in PubMed, 550 in MEDLINE, five in LILACS, and one in BDENF. We selected 15 articles after screening them according to the inclusion and exclusion criteria and analysis of titles and abstracts; ten studies were found in PubMed, four in MEDLINE, and one in LILACS, as shown in Figure 1.

The level of evidence of the summarized sample publications was adopted in the analysis according to the classification:

• Level I (systematic review or meta-analysis of multiple control studies);
• Level II (single study with experimental design);
• Level III (study with a quasi-experimental design, such as non-randomized trial with a single pre- and post-test group, time series, or case-control);
• Level IV (study with non-experimental design, such as descriptive correlational and qualitative research or case studies);

Figure 1. Flowchart of the identification and selection of scientific articles.
- Level V (case report or data obtained systematically with verifiable quality or program evaluation data);
- Level VI (opinion of reputable authorities based on clinical competence or opinion of expert committees, including interpretations of non-research-based information)

**RESULTS**

The sample includes 15 articles, characterized in Chart 1, according to the numerical order of publications, author/year, country of origin, method, database, journal, and level of evidence.

We underline that 13 articles were written in English, two in Spanish, and all were published in 2020. Seven works were conducted in the United States, three in China, one in Chile, one in Japan, one in Portugal, one in Spain, and one in India. Articles A4 and A10 were published in the same journal, namely, the Journal of Clinical Anesthesia. Several methods were applied to the studies, especially clinical recommendations, with nine articles (A1, A2, A4, A6, A8, A9, A10, A11, A14), followed by four case reports (A3, A5, A7, A15), and two observational studies (A12 and A13). Ten publications

<td>Aranda et al.² Recommendations for the management of COVID-19 patients in the perioperative period</td>
<td>To provide recommendations for anesthesia management of patients with suspected or confirmed COVID-19 infection in the perioperative period in order to reduce the risk of infection for health professionals, other patients, and the community.</td>
<td>Protective masks (preferably N95, FFP2, or equivalent) for the health team; goggles; surgical gowns with impermeable sleeves and cuffs; non-sterile and well-fitting gloves (latex or nitrile); use of double gloves for airway manipulation. Coordinate patient transfer with the hospital safety system to achieve optimal flow; maintenance of the surgical mask for patients submitted to local anesthesia.</td>
<td>Recommendations include training the multidisciplinary team, adequate disposal of contaminated waste, using personal protective equipment (PPE), and strategies for managing airways and anesthesia administration.</td>
</tr>
<tr>
<td>Krishnamoorthy et al.⁸ Rational perioperative utilisation and management during the COVID-19 pandemic</td>
<td>To report the elaboration of a structure for the next steps needed to prepare perioperative teams for an outbreak of critical patients due to COVID-19.</td>
<td>Detailed planning for the health system.</td>
<td>The authors suggest detailed planning for the health system, considering local organizational factors. Important considerations include: a) what types of severely ill patients will be treated in the perioperative period?; b) how will perioperative professionals be prepared to care for critical patients?; c) what organizational infrastructure, including intensivist consultation and regionalization of care, will work best in the local environment?</td>
</tr>
<tr>
<td>Yek et al.⁹ Perioperative considerations for COVID-19 patients: lessons learned from the pandemic</td>
<td>To facilitate the surgical management of patients with confirmed or suspected COVID-19 while minimizing the risk of nosocomial transmission to healthcare workers and other patients.</td>
<td>Considerations on the equipment and facilities in the perioperative management of COVID-19 patients: a) patient transportation with plastic cover; b) example of personal protective equipment; c) workflow of the operating room complex; powered air-purifying respirator (PAPR); PPE: N95 masks, face shield, disposable gowns, additional green cape to protect the neck and ears.</td>
<td>Detailed planning and coordination between departments are necessary to reduce the risk of transmission. Containment measures must be effective but practical, without compromising patient care, especially during a surgical emergency.</td>

had level of evidence VI (A1, A2, A4, A5, A6, A8, A9, A10, A11, A14), four had level V (A7, A12, A13, A15), and only one had level IV (A3).

Chart 2 summarizes the articles that comprise the sample, according to title, objectives, recommendations, and conclusions.

Chart 2 shows that the words surgery, perioperative, and COVID-19 were prevalent in the titles of publications that composed this integrative review and that the recommendations highlighted the use of personal protective equipment (PPE) to reduce the risk of infection among patients and professionals.

## DISCUSSION

Analysis of the selected articles revealed that the publications presented the main difficulties for the multidisciplinary team to keep the SC working during the COVID-19 pandemic. Due to the high infectivity and transmissibility of SARS-CoV-2, hospitals, intensive care units, and operating rooms in several countries were faced with high bed occupancy, which is a concern for professionals and forces them to reflect on new techniques and effective strategies to reverse the overwhelming scenario of the COVID-19 pandemic.

Therefore, the hospital staff should plan, coordinate, and provide training to minimize the risk of infection for professionals, particularly the perioperative care team, since they are most likely to come into contact with droplets, aerosols, and body fluids during their practice, needing to postpone elective surgeries.

We highlight an example of this susceptibility in the SC, involving the treatment of the first identified case of a patient with COVID-19 submitted to surgery in Wuhan, China, as all 14 professionals in the surgical block were infected because they did not take the proper precautions.

Thus, researchers inferred that huddles allow them to share information about the risk of aerosolization. Discussions about the use of PPE, the preparation of procedures in advance, patient transportation to the operating room, and the location of post-procedure recovery were beneficial, helping to coordinate the multidisciplinary team and improving planning, decision-making, and perioperative safety.

In addition, safety measures should be reinforced during the pandemic period. The use of PPE in the presence of a surgical patient infected with COVID-19 is imperative for the safety of professionals. Studies describe PPE as: protective mask (N95), goggle, face shield, surgical gown with impermeable sleeves and cuffs, non-sterile well-fitting glove, double gloves for airway manipulation, shoe covers, additional cape to protect the neck and ears.

Corroborating this finding, researchers added the use of “special surgical garments”, helmets, PPE, among others, in orthopedic surgical positioning. They also detailed the
division of the sector into zones to avoid spreading the virus to other environments and other professionals\textsuperscript{12}.

A clean environment proved to be crucial in this scenario so as to avoid cross-contamination. Removing the clothes used by the patient must be done carefully, and special attention should be paid to the disinfection of beds, stretchers, and other transport equipment. The team can also cover materials and equipment with plastics and clean them with proper detergents/decontaminating products\textsuperscript{5,13}.

Other precautions should also be taken, such as washing hands with water and soap or chlorhexidine before and after contact with the patient and during the change of clothes. The operating room should have negative-pressure ventilation and high-efficiency particulate air (HEPA) filters\textsuperscript{15}.

We emphasize that the risk of infection in the hospital environment increases while donning, doffing, and disposing of the equipment at the end of the procedure, so training and preparing the team for this practice is crucial\textsuperscript{5,15}.

Patient transportation should be done with caution, given the risk of aerosolization; therefore, the N95 mask should be used to avoid spreading infected droplets. Communication between professionals during this transportation and instructions to leave the transport route free are considered essential\textsuperscript{11}.

Other studies recommend that, in addition to using a mask, the patient be fully pre-oxygenated before anesthetic induction and that tracheal intubation be performed quickly, using a laryngoscope after the induction of fast-acting muscle relaxants, in order to avoid coughing, with monitoring of vital signs. Extubation and post-anesthesia recovery should also be performed in the operating room to expose the lowest number of professionals\textsuperscript{11,13,14}.

Researchers listed some precautions in the surgical preparation of patients with suspected COVID-19, namely: signage specifying the patient transport route; transporting the patient with supplemental oxygen through a face mask in a trolley covered by plastic that should be removed upon entering the operating room; mechanical ventilation and intubation to support the airway through videolaparoscopy, and general anesthesia maintained with desflurane\textsuperscript{6}.

Other recommendations include controlling the patient’s hemostasis during surgery so as to prevent blood around the surgical incision, as well as reducing irrigation and drainage to avoid the splashing of blood and body fluids. In addition, tracheal intubation, sputum aspiration, and the use of other electrosurgical equipment should be performed with extreme caution since aerosols can remain in the air for a long time\textsuperscript{19}.

Some studies emphasize that the excessive number of professionals in the same site increases the exposure and risk of coronavirus infection, leading to the disproportionate use of PPE\textsuperscript{10,14,16}. An investigation estimates that the operating room should have no more than two surgeons, one anesthesiologist, two nursing professionals, and one surgical technologist\textsuperscript{6}.

Researchers have published guidelines regulating surgical procedures and showing the great concern of professionals regarding the postponement of elective surgeries. Therefore, its risk-benefit should be assessed, as it involves the patient’s health, safety, and well-being. Logistic factors should also be considered, including the lack of hospital beds, availability of intensive care, adequacy of labor, and availability of material resources\textsuperscript{6,15,16}.

Given this context, professionals should pay attention to the screening process before an emergency surgical procedure, as in cases of patients victims of severe traumatic brain injury. Some authors indicate the need to investigate epidemic contact and for prompt preoperative tests in order to rule out the possibility of coronavirus infection since some symptoms that manifest after traumatic brain injury can be mistaken for those of COVID-19\textsuperscript{19}.

The preoperative screening process performed in patients undergoing spinal surgery stands out, taking into account the severity of the condition, the screening for hyperthermia, the X-ray result and the chest computed tomography in 24 hours to detect lung abnormalities, the reverse transcription test followed by polymerase chain reaction (RT-PCR), and the serology. The use of large equipment was also considered, as it is difficult to disinfect after the procedure. In addition, electric-powered devices that generate surgical smoke, such as burrs, drills, and oscillating saws, are often used, favoring the circulation of aerosol particles\textsuperscript{19}.

In line with the information above, researchers reported that, by adopting the standard precautions of proper distancing, careful screening, surface cleaning, and use of N95 mask, they did not need to suspend surgical procedures
for cancer patients during the pandemic, preventing these cases from becoming inoperable\textsuperscript{18}.

A study drew attention to the very low prevalence of asymptomatic positive patients in a large population that needed to undergo a surgical procedure\textsuperscript{20}. To this end, all patients scheduled for surgery and who circulated in perioperative areas underwent a preoperative RT-PCR test with results available in no more than two days, reducing the exposure time. Researchers reason that surgeons and other professionals must know and interpret the types of tests available and how the results influence their practice\textsuperscript{14,20}.

One study suggested a COVID-19 test protocol for patients with scheduled surgeries. In addition to patient screening, professionals can also be tested, ensuring more safety in the contact between professionals and patients\textsuperscript{20}.

So far, there is no specific treatment to combat SARS-CoV-2. However, care should be directed to managing signs, symptoms, and complications, such as: respiratory support, septic shock treatment, and antimicrobial treatment in cases of acquired pneumonia, according to clinical guidelines specific to each facility\textsuperscript{14}.

Researchers emphasize that the nursing team has adapted to changes in standards and routines as the need arose due to intensive care training and improvement in the use of PPE\textsuperscript{21}. Two studies underlined that routine follow-ups and drug prescriptions could be performed by e-mail, telephone, videoconference, and other portals created by each establishment\textsuperscript{15,16}.

This scenario benefits the reorganization of policies and promotes changes in the physical structure, management training, perioperative and intensive care of the work environment. Authors defend the calculation and evaluation of epidemiological data to balance the supply of services with the demand of each site\textsuperscript{8}.

Thus, the articles analyzed provide effective knowledge and experiences related to the maintenance of surgeries in hospital facilities during the COVID-19 pandemic in 2020. Such findings can be used by scholars and professionals. The defined time frame and the lack of articles in Portuguese are considered study limitations.

\section*{Conclusion}

By analyzing the 15 publications, we found that the COVID-19 pandemic has been a major challenge for health professionals, the population, and public policies, given the impactful and novel nature of the disease, with many complications to the patient, and the knowledge changes brought by something new. The implementation of short-term strategies was considered, with few alternatives that could ensure the lowest number of people infected. The research addressed the main safety measures used in the surgical block, in addition to administrative recommendations that could guide the planning of the work process, justifying the importance of this integrative review.

Therefore, we suggest that managers, health professionals, and students assimilate this theme, consider the possibility of limiting elective surgical procedures, and, above all, facilitate access to COVID-19 tests and the use of PPE, as well as support professionals by providing update training courses, simulations, etc. We stress that each country has its limitations and specificities and, therefore, protocols should be adapted according to the context of each location, taking into account epidemiological data, financial transfer, culture, among other aspects.
